

SPECIFICATION

HOCKEY STICK

RELATED APPLICATIONS

[0001] This application is a continuation in part of United States Patent Application Serial Number 10/439,652 filed on May 15, 2003 and claims priority thereto, the contents of which are hereby incorporated by reference.

FIELD OF THE INVENTION

[0002] The field of the present invention generally relates to hockey sticks including hockey stick configurations, manufacture and component structures and combinations thereof.

10

BACKGROUND OF THE INVENTION

[0003] Generally, hockey sticks are comprised of a blade portion and an elongated shaft portion. Traditionally, each portion was constructed of wood (e.g., solid wood, wood laminates) and attached together at a permanent joint. The joint generally comprised a slot formed by two opposing sides of the lower end section of the shaft with the slot opening on the forward facing surface of the shaft. As used in this application "forward facing surface of the shaft" means the surface of the shaft that faces generally toward the tip of the blade and is generally perpendicular to the longitudinal length of the blade at the point of attachment. The heel of the blade comprised a recessed portion dimensioned to be receivable within the slot. Upon insertion of the blade into the slot, the opposing sides of the shaft that form the slot overlap the recessed portion of the blade

at the heel. The joint was made permanent by application of a suitable bonding material or glue between the shaft and the blade. In addition, the joint was oftentimes further strengthened by an overlay of fiberglass material.

[0004] Traditional wood hockey stick constructions, however, are expensive to

5 manufacture due to the cost of suitable wood and the manufacturing processes employed. In addition, due to the wood construction, the weight may be considerable. Moreover, wood sticks lacked durability, often due to fractures in the blade, thus requiring frequent replacement. Furthermore, due to the variables relating to wood construction and manufacturing techniques, wood sticks were often difficult to manufacture to consistent tolerances. For example, the curve 10 and flex of the blade often varied even within the same model and brand of stick. Consequently, a player after becoming accustomed to a particular wood stick was often without a comfortably seamless replacement when the stick was no longer in a useable condition.

[0005] Notwithstanding, the "feel" of traditional wood-constructed hockey sticks was

found desirable by many players. The "feel" of a hockey stick can vary depending on a myriad of 15 objective and subjective factors including the type of construction materials employed, the structure of the components, the dimensions of the components, the rigidity or bending stiffness of the shaft and/or blade, the weight and balance of the shaft and/or blade, the rigidity and strength of the joint(s) connecting the shaft to the blade, the curvature of the blade, the sound that is made when the blade strikes the puck, etc. Experienced players and the public are often inclined to use 20 hockey sticks that have a "feel" that is comfortable yet provides the desired performance. Moreover, the subjective nature inherent in this decision often results in one hockey player

preferring a certain "feel" of a particular hockey stick while another hockey player prefers the "feel" of another hockey stick.

[0006] Perhaps due to the deficiencies relating to traditional wood hockey stick constructions, contemporary hockey stick design veered away from the traditional permanently attached blade configuration toward a replaceable blade and shaft configuration, wherein the blade portion was configured to include a connection member, often referred to as a "tennon", "shank" or "hosel", which generally comprised of an upward extension of the blade from the heel. The shafts of these contemporary designs generally were configured to include a four-sided tubular member having a connection portion comprising a socket (e.g., the hollow at the end of the tubular shaft) appropriately configured or otherwise dimensioned so that it may slidably and snugly receive the connection member of the blade. Hence, the resulting joint generally comprised a four-plane lap joint. In order to facilitate the detachable connection between the blade and the shaft and to further strengthen the integrity of the joint, a suitable bonding material or glue is typically employed. Notable in these contemporary replaceable blade and shaft configurations is that the point of attachment between the blade and the shaft is substantially elevated relative to the heel attachment employed in traditional wood type constructions.

[0007] Although over the years, metallic materials such as aluminum were employed to form tubular shafts adapted to being joined to replaceable blades in the manner described above; in more recent years the hockey stick industry has tended to make more and more hockey stick shafts from composite materials. Such shafts, for example, have been manufactured via pultrusion or by wrapping layers of composite fibers over a mandrel and then curing so that the fibers reside in a hardened resin matrix. Although, composite hockey stick shafts are much

appreciated by players for their performance attributes, applicants have found that they tend to transmit undesirable vibration more efficiently to the player's hands than did traditional wood constructed hockey sticks.

[0008] Contemporary replaceable blades, of the type discussed above, are constructed of various materials including wood, wood laminates, wood laminate overlain with fiberglass, and what is often referred to in the industry as "composite" constructions. Such composite blade constructions employ what is generally referred to as a structural sandwich construction, which comprises a low-density rigid core faced on generally opposed front and back facing surfaces with a thin, high strength, skin or facing. The skin or facing is typically comprised of plies of woven and substantially continuous fibers, such as carbon, glass, graphite, or Kevlar™ disposed within a hardened matrix resin material. Of particular importance in this type of construction is that the core is strongly or firmly attached to the facings and is formed of a material composition that, when so attached, *rigidly* holds and separates the opposing faces. The improvement in strength and stiffness, relative to the weight of the structure, that is achievable by virtue of such structural sandwich constructions has found wide appeal in the industry and is widely employed by hockey stick blade manufacturers.

[0009] Contemporary composite blades are typically manufactured by employment of a resin transfer molding (RTM) process, which generally involves the following steps. First, a plurality of inner core elements composed of compressed foam, such as those made of polyurethane, are individually and together inserted into one or more woven-fiber sleeves to form an uncured blade assembly. The uncured blade assembly, including the hosel or connection member, is then inserted into a mold having the desired exterior shape of the blade. After the

mold is sealed, a suitable matrix material or resin is injected into the mold to impregnate the woven-fiber sleeves. The blade assembly is then cured for a requisite time and temperature, removed from the mold, and finished. The curing of the resin serves to encapsulate the fibers within a rigid surface layer and hence facilitates the transfer of load among the fibers, thereby

5 improving the strength of the surface layer. In addition, the curing process serves to attach the rigid foam core to the opposing faces of the blade to create -- at least initially -- the rigid structural sandwich construction.

[0010] Experience has shown that considerable manufacturing costs are expended on the woven-fiber sleeve materials themselves, and in impregnating those fiber sleeves with resin while

10 the uncured blade assembly is in the mold. Moreover, the process of managing resin flow to impregnate the various fiber sleeves, has been found to, represent a potential source of manufacturing inconsistency. In addition, as was the case with composite shaft constructs, such composite blade constructs tend to transmit undesirable vibrations to the player's hands, especially when coupled to a composite shaft. In this regard, commonly owned U.S. patent application serial

15 number Serial 10/439,652 filed on May 15, 2003, hereby incorporated by reference, teaches a hockey stick construction comprising a composite blade construct having one or more core elements formed of a resilient elastomer material (e.g., rubber) which may serve to dampen vibration, while also providing desirable performance attributes.

[0011] Composite shafts and blades, nonetheless, are thought to have certain advantages

20 over wood shafts and blade. For example, composite blades and shafts may be more readily manufactured to consistent tolerances and are generally more durable than their wood

counterparts. In addition, such composite constructs are capable of providing improved strength and hence may be made lighter.

[0012] Notwithstanding, such constructions nevertheless also have been found by applicants to produce a "feel" and/or performance attributes (e.g., vibration, sound, flex) that are 5 unappealing to some players. Even players that choose to play with composite hockey sticks continually seek out alternative sticks having improved feel or performance. Moreover, despite the advent of contemporary composite hockey stick constructions and two-piece replaceable blade-shaft configurations, traditional wood-constructed hockey sticks are still preferred by many players notwithstanding the drawbacks noted above. In an on going effort to improve the state of 10 the technology, applicants disclose unique composite hockey stick configurations and constructions that may overcome one or more of these deficiencies.

SUMMARY OF THE INVENTION

[0013] The present invention relates to hockey sticks, their manufacture, configuration and component structures. Various aspects are set forth below.

15 [0014] In one aspect, a hockey stick comprises a tubular hollow rectangular shaft having an outer layer and inner layer formed of composite molded around an elastomer middle layer. The elastomer middle layer may be positioned any where along the longitudinal length of the shaft, however, it is contemplated that the elastomer layer be configured reside nearer the blade of the hockey stick within preferred positions described herein. Similarly, although it contemplated that 20 the elastomer middle layer form at least a portion of each of the four walls that comprise the

rectangular shaft, the middle elastomer layer may form any one of the four walls or all of the four walls or any combination of one or more of the four walls.

[0015] In another aspect, a method for manufacturing a composite hockey stick blade is disclosed comprising (a) providing a cured tubular shaft, such as the one previously set forth above, (b) providing an un-cured composite blade comprising one or more core elements wrapped with one or plies of fibers dimensioned to receive the lower portion of the hockey stick shaft, (c) inserting the cured shaft into the un-cured hockey stick blade, and (d) curing the composite blade around the cured hockey stick shaft.

[0016] Additional implementations, features, variations, and advantageous of the invention will be set forth in the description that follows, and will be further evident from the illustrations set forth in the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0017] The accompanying drawings illustrate presently contemplated embodiments and constructions of the invention and, together with the description, serve to explain various principles of the invention.

[0018] **FIG. 1** is a diagram illustrating a representative hockey stick configuration.

[0019] **FIG. 2** is a rear view of a lower portion of the hockey stick illustrated in FIG. 1

[0020] **FIG. 3** is a back face view of the hockey stick blade illustrated in FIG. 1 detached from the hockey stick shaft.

[0021] **FIG. 4** is a rear view illustration taken along line 4—4 of the hockey stick blade illustrated in FIG. 3.

[0022] **FIG. 5** is a top view illustration taken along line 5—5 of the hockey stick blade illustrated in FIG. 3.

5 [0023] **FIG. 6** is a front side view of the hockey stick shaft illustrated in FIG. 1 detached from the blade.

[0024] **FIG. 7** is an enlarged partial rear view of the hockey stick shaft illustrated in Fig. 6.

[0025] **FIG. 8** is an enlarged partial front view of the hockey stick shaft illustrated in FIG. 6.

10 [0026] **FIG. 9** is an enlarged bottom end view of the hockey stick shaft illustrated in FIG. 6

[0027] **FIG. 10** is a cross-sectional view of the hockey stick shaft illustrated in Fig. 6 taken along line 10—10.

15 [0028] **FIG. 11** is an enlarged perspective view of the cross-section illustrated in FIG. 11, showing the composite structure of lay-up of the shaft at line 10---10, with successive layers serially exposed.

[0029] **FIG. 12** is a cross-sectional view of the hockey stick shaft illustrated in FIG. 6 taken along line 11—11.

[0030] **FIG. 13** is an enlarged perspective view of the cross-section illustrated in FIG. 11, showing the composite structure of a preferred lay-up of the shaft at line 11---11, with successive layers serially exposed.

[0031] **FIG. 14** is a representative cross-sectional view taken along line 14---14 of FIG. 3 illustrating the internal construction of the detached hockey stick blade at the mid-region..

[0032] **FIG. 15** is a representative cross-sectional view taken along line 15---15 of FIG. 3 illustrating the internal construction of the hockey stick blade at the heel region.

[0033] **FIG. 16A-C** are flow charts detailing preferred steps for manufacturing the hockey stick illustrated in FIGs 1-15 and the component elements thereof.

10 [0034] **FIG. 17** is a diagram of the spacer element being removed from the pre-cured hockey stick blade illustrated in FIG. 3.

[0035] **FIG. 18** is a diagram of the cured hockey stick shaft being inserted into the pre-cured hockey stick blade illustrated in FIG. 3.

15 [0036] **FIG. 19** is a diagram of the uncured hockey stick blade and the cured hockey stick shaft assembled in the open mold prior to curing.

[0037] **FIG. 20** is a diagram of the uncured hockey stick blade and the cured hockey stick shaft assembled in the closed mold prior to curing.

[0038] **FIG. 21** is a front side view diagram of the hockey stick illustrated in FIG. 1 illustrating the length of the hockey stick (L-HS) and the length of the hockey stick shaft (L-S) and longitudinal distances (L1 and L2) for placement of elastomer layer in the shaft.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

5 [0039] The preferred embodiments will now be described with reference to the drawings. To facilitate description, any reference numeral designating an element in one figure will designate the same element if used in any other figure. The following description of the preferred embodiments is only exemplary. The present invention(s) is not limited to these embodiments, but may be realized by other implementations. Furthermore, in describing preferred embodiments,
10 specific terminology is resorted to for the sake of clarity. However, the invention is not intended to be limited to the specific terms so selected, and it is to be understood that each specific term includes all equivalents.

[0040] FIGs. 1-21 are diagrams illustrating the configuration, structure, construction, and manufacture of a representative hockey stick **10** and components thereof. Generally FIGs. 1 and 2 illustrate the representative hockey stick **10** comprising a shaft **20** and the blade **30** joined to one another; FIGs. 3-5 illustrate the external configuration of the blade **30** detached from the shaft **20**; FIGs. 14-15 illustrate the internal configuration and structure of the blade **30**; FIGs. 6-9 illustrate the external configuration of the shaft **20** detached from the blade **30**; FIGs. 10-13 illustrate the internal configuration and structure of the shaft **20**, FIGs. 16a-16c are flow charts detailing
15 preferred steps for manufacturing the representative hockey stick **10**; FIGs. 17-20 are diagrams illustrating various aspects of the manufacturing process set forth in Figs. 16a -16c and also

further illustrate the structure and construction of the shaft **20** and blade **30**, and lastly FIG. 21 is a diagram employed in conjunction with describing presently preferred locations of the elastomer middle layer (described in more detail below) along the longitudinal length of the shaft **20** of the representative hockey stick **10**. Each of the figures is further described in detail below in the 5 foregoing order.

[0041] FIGs. 1 and 2 are diagrams illustrating a representative hockey stick **10** configuration comprising a blade **30** and a shaft **20** joined thereto. Externally, the blade **30** comprises a lower section **70**, an upper section **80**, a front face wall **90**, a back face wall **100**, a bottom edge **110**, a top edge **120**, a tip section **130**, and a heel section **140**, which generally resides 10 behind the tip section **130** of the blade **30** between the plane defined by the top edge **120** and the plane defined by the bottom edge **110** of the blade **30**. The heel section **140** of the blade **30** includes a slot **145** that extends internally between the front face wall **90** and back face wall **100** of the blade **30** and tapers or narrows as it extends from between the top edge **120** toward the bottom edge **110** of the blade **30** (best illustrated in FIG. 5). The internal construction of the blade **30** is 15 described in more detail in subsequent portions of this description in relation to FIGs. 14 and 15 and the manufacturing process described in relation to FIGs. 16a-16c and 17-20.

[0042] The shaft **20** comprises an upper section **40**, a mid-section **50**, and a lower section **60**, which is adapted to being interposed or joined within the slot **145** located in the heel section **140** of the blade **30** between the front face wall **90** and back face wall **100** of the blade **30**. In the 20 preferred embodiment, illustrated in the drawings, the shaft **20** is generally rectangular in cross-section with two wide opposed walls **150** and **160** and two narrow opposed walls **170** and **180**. Narrow wall **170** includes a forward-facing surface **190** and narrow wall **180** includes a rearward-

facing surface **200**. The forward-facing surface **190** faces generally toward the tip section **130** of the blade **30** and is generally perpendicular to the longitudinal length of the blade **30** (i.e., the length between the heel section **140** and the tip section **130**). The rearward-facing surface **200** faces generally away from the tip section **130** of the blade **30** and is also generally perpendicular to the longitudinal length of the blade **30**. Wide wall **150** includes a front-facing surface **210** and wide wall **160** includes a back-facing surface **220**. When the shaft **20** is attached to the blade **30** as illustrated in FIGs. 1 and 2, the front-facing surface **210** faces generally in the same direction as the front face wall **90** of the blade **30** and the back-facing surface **220** faces generally in the same direction as the back face wall **100** of the blade **30**.

10 [0043] In the preferred embodiment, the shaft **20** includes a tapered section **330** (best illustrated in Figs. 2, 7 and 8) having a reduced shaft width. The "shaft width" is defined for the purposes of this application as the dimension between the front and back facing surfaces **210** and **220**. The tapered section **330** is dimensioned so that, when the shaft **20** is assembled to the blade **30** prior to curing of the blade **30**, the portions of the front and back facing surfaces **210**, **220** of 15 the shaft **20** configured to being interposed within slot **145** are dimensioned to fit within the slot **145** of the blade **30**. The adjacent, more upwardly positioned portions of the front and back facing surfaces **210**, **220** of the shaft **20** are dimensioned so that they are flush with the adjacent portions of the front and back face walls **90** and **100** of the blade **30** residing there below.

[0044] Hence, the heel section **140** of the blade **30** includes an open-ended slot **145** that is 20 dimensioned to receive the lower portion of the tapered section **330** of the shaft **20** having a reduced width. Corresponding and opposed shoulders **280** and **290** in the shaft **20** and blade **30** configured to reside at the transition there between facilitate the transition between the shaft **20**

and the blade **30**. Hence, when the shaft **20** is inserted into the slot **145** of the blade **30**, shoulders **280** and **290** are configured to be in opposed alignment so that they may abut with one another.

[0045] FIGs. 3-5 further illustrate the external configuration of the blade **30**, including the slot **145**, the front and back facing walls **90** and **100** of the blade **30** that form the slot **145** and the shoulder **290** of the blade **30**, which is configured to generally abut with the shoulder **280** of the shaft **20**. FIGs. 6-9, on the other hand further illustrate the external configuration of the shaft **20**. Notably, in the representative implementation of the hockey stick **10**, the shaft **20** is formed as a hollow tubular structure that is defined by opposed wide walls **150** and **160** and opposed narrow walls **170** and **180**. The hollow **230** of the shaft **20** is configured, in the representative implementation, to extend generally the full longitudinal length of the shaft **20** -- from the upper section **40** to the lower section **60**, which is tapered as it extends to its conclusion. The taper in the lower section is accomplished by reducing the width of the shaft **20** between the opposed wide walls **150** and **160** or in other words by reducing the width of opposing narrow walls **170** and **180**. Notably, the width of the opposing wide walls **150** and **160** of the shaft are, in the representative implementation, generally uniform in dimension as the shaft extends from the upper section **40** toward the lower section **60**. However, it is contemplated that the width of wide walls **150** and/or **160** may be varied at any given region.

[0046] FIGs. 10-13 illustrate a presently preferred shaft **20** structure. As previously noted, the shaft **20** is generally rectangular hollow tubular structure defined by opposing side walls **150** and **160** and opposing narrow walls **170** and **180**. Generally the shaft **20** comprises an inner layer **410**, an outer layer **430**, and a middle elastomer layer **420**. The inner and outer layers **410** and **430** are molded around the middle elastomer layer **420**. As best illustrated in FIGs. 10-13, the inner

layer **410** is preferably constructed to have a greater cross-sectional thickness than the outer layer **430**. A preferred construction of the shaft **20** comprises an inner and outer layers **410** and **430**, each of which comprising a plurality of plies of parallel fibers or filaments oriented in one or more defined directions relative to the longitudinal length of the shaft **20** and disposed in a hardened resin matrix. As used herein, the term "ply" shall mean a group of fibers largely parallel to one another and running in a single direction, and which may or may not be interwoven with or stitched to one or more other groups of fibers, of which each group may or may not be oriented in a different direction. Hence a ply may comprise un-directional fibers all running in a single direction, groups of woven or weaved fibers, with one group of fibers running in a first direction parallel with one another and another group of fibers woven or weaved with the first running in a second direction parallel with one another. Unless otherwise defined, a "layer" shall mean one or more plies that are laid down together or over one another to form a definable wall structure.

[0047] An exemplary hockey stick shaft lay-up for the inner and outer layers **410** and **430** are set forth in the tables below:

15

Table: Inner Layer Lay-Up

<u>Fiber Orientation</u>	<u>Fiber</u>	<u>Number of Plies</u>
+ 45	Carbon	7
- 45	Carbon	7
0	Carbon	4 Interposed between consecutive +/- 45 plies

Table: Outer Layer Lay-Up

<u>Fiber Orientation</u> (From Inner most ply to Outer most ply)	<u>Fiber</u>	<u>Number of Plies</u>
0	Carbon	1
+ 45	Carbon	1
- 45	Carbon	1
0/90	Woven Carbon	1
0/90	Woven aramid	1

[0048] Hence in a preferred construction of the shaft 20, the inner layer 410 comprises eighteen (18) plies of parallel fibers; whereas the outer layer 430 comprises only five (5) plies of 5 parallel fibers. Hence the outer layer 430 is on the order of approximately 1/4 to 1/3 the thickness of the inner layer 410 or in other words the inner layer 410 is three to four times thicker than the outer layer 430. Furthermore, it is noted that the outer most ply of the outer layer 430 is woven.

[0049] Although carbon and aramid (such as Kevlar™ manufactured by Dupont Corporation) fibers are employed in the foregoing representative lay-ups of the outer and/or inner 10 layers 430 and 410 of the shaft 20, it is to be understood that other fibers or filaments may be employed. Thus for example, it is contemplated that in addition to carbon and aramid fibers, fibers made of glass, polyethylene (such as Spectra™ manufactured by Allied Signal Corporation), ceramic (such as Nextel™ manufactured by 3m Corporation), boron, quartz, polyester or any other fiber that may provide the desired strength may be employed. Preferably, at least part of one of 15 the fibers is selected from the group consisting of carbon fiber, aramid, glass, polyethylene,

ceramic, boron, quartz, and polyester; even more preferably from the group consisting of carbon fiber, aramid, glass, polyethylene, ceramic, boron, and quartz; yet even more preferably from the group consisting of carbon fiber, aramid, glass, polyethylene, ceramic, and boron; yet even more preferably from the group consisting of carbon fiber, aramid, glass, polyethylene, and ceramic; yet even more preferably from the group consisting of carbon fiber, aramid, glass, and polyethylene; yet even more preferably from the group consisting of carbon fiber, aramid, and glass; yet even more preferably from the group consisting of carbon fiber and aramid; and most preferably comprises carbon fiber.

[0050] It has been found preferable, as can be surmised from the foregoing tables, that it is preferable for the lay-up of the shaft to include groups of parallel fibers oriented in different directions. Hence, for example the plurality of plies that form inner layer 410 include plies having uni-directional fibers oriented in a first direction and plies having uni-directional fibers oriented in a second direction that is different than the first.

[0051] The matrix or resin-based material in which the fibers are disposed may be selected from a group including: (1) thermoplastics such as polyether-ketone, polyphenylene sulfide, polyethylene, polypropylene, urethanes (thermoplastic), and Nylon-6, and (2) thermosets such as urethanes (thermosetting), epoxy, vinyl ester, polycyanate, and polyester. In the preferred construction set forth above thermoset resins have been satisfactorily employed.

[0052] In addition, it has been found preferable that the plies of fibers be pre-impregnated with a resin prior to being layered over one another and the mandrel. By so doing, it has been found that the lay-up of the plies is facilitated in that each ply is capable of acting as a tape and adhering to the preceding ply and hence may serve to facilitate the fixing of the relative position of

the pre-cured plies to one another. In this regard, suitable materials include: (a) uni-directional carbon fiber tape pre-impregnated with epoxy, manufactured by Hexcel Corporation of Salt Lake City, Utah, and also S & P Systems of San Diego, California, (b) uni-directional glass fiber tape pre-impregnated with epoxy, also manufactured by Hexcel Corporation, (c) uni-directional 5 Kevlar™ fiber tape pre-impregnated with epoxy, also manufactured by Hexcel Corporation, (d) 0/90 woven Kevlar™ fiber tape pre-impregnated with epoxy, also manufactured by Hexcel Corporation, and (e) 0/90 woven carbon tape pre-impregnated with epoxy, also manufactured by Hexcel corporation.

[0053] With respect to the middle elastomer layer, the term "elastomer" or "elastomeric", 10 as used herein, is defined as, or refers to, a material having properties similar to those of vulcanized natural rubber, namely, the ability to be stretched to at least approximately twice its original length and to retract rapidly to approximately its original length when released. Hence, materials that fall within the definition of "elastomeric" as used and described herein include materials that have an ultimate elongation equal to or greater than 100% in accordance with the 15 following formula:

$$(1) \quad \text{Ultimate Elongation Percentage} = \{[(\text{final length at rupture}) - (\text{original length})] \div [\text{original length}]\} \times 100$$

Where: Ultimate Elongation: also referred to as the breaking elongation, is 20 the elongation at which specimen rupture occurs in the application of continued tensile stress as measured in accordance with ASTM Designation D 412 Standard Test Methods for Vulcanized Rubber and Thermoplastic Elastomers - Tension (August 1998).

[0054] Such elastomer materials may include: (1) vulcanized natural rubber; (2) synthetic thermosetting high polymers such as styrene-butadiene copolymer, polychloroprene (neoprene), nitrile rubber, butyl rubber, polysulfide rubber ("Thiokol"), cis-1, 4-polyisoprene, ethylene-propylene terpolymers (EPDM rubber), silicone rubber, and polyurethane rubber, which can be 5 cross-linked with sulfur, peroxides, or similar agents to control elasticity characteristics; and (3) Thermoplastic elastomers including polyolefins or TPO rubbers, polyester elastomers such as those marketed under the trade name "Hytrel" by E.I. Du Pont; ionomer resins such as those marketed under the trade name "Surlyn" by E.I. Du Pont, and cyclic monomer elastomers such as di-cyclo pentadiene (DCPD).

10 [0055] In addition, one criteria for assessing the appropriateness of an elastomer is its ability to be molded to the materials that form the inner and outer layers between which it is disposed. In the exemplary hockey shaft construction described above, it has been found that the following exemplary elastomer is capable of being employed successfully:

	Material:	Styrene Butadiene Rubber Latex
15	Supplier:	Diversified Materials Company, La Mesa, California
	Hardness HS (JIS-A):	65+/-5
	Elongation Percentage:	200 or above
	Tensile Strength:	100 Kgf/cm ² or above
	180 Peel Value:	10 kgf/25mm or above
20	Weight:	180 g/m ²

[0056] Notably, applicants have found that the employment of intermediate elastomer layer in a composite hockey stick shaft may impact or dampen the vibration typically produced from such shafts and thereby provides a means for controlling or tuning the vibration to produce or more desirable feel.

5 [0057] FIG. 16B is a flow chart detailing preferred steps for manufacturing the hockey stick shaft 20, prior to joining the shaft 20 to the blade 30 in accordance with the preferred manufacturing process described in FIG. 16A. In general a mandrel, dimensioned to have the desired internal dimensions of the tubular hollow 230 of the shaft 20, is provided (step 600). The mandrel is overlaid with a plurality of pre-impregnated plies of fibers which forms the inner layer 10 410 of the hockey stick shaft 20 (step 605). The inner layer 410 is then overlaid, at the desired location or locations, with a sheet of elastomer material, which forms the middle elastomer layer 420 of the hockey stick shaft 20 (step 610). The middle elastomer layer 420 is then overlaid with a plurality of pre-impregnated fiber plies, which form the outer layer 430 of the hockey stick shaft 20 (step 615). The un-cured shaft pre-form is then placed within a female mold and heat is 15 applied to cure the shaft 20 over the mandrel. The mandrel is then removed from the cured shaft 20 (step 625).

20 [0058] The middle elastomer layer 420 may extend the full longitudinal length of the shaft 20 and/or on each of the four side walls (i.e. wide walls 150 and 160 and narrow walls 170 and 180) of the shaft 20 at any given cross-section of the shaft 20. It is contemplated, however, that the middle elastomer layer 420 may extend only along one or more discrete longitudinal portions 20 of the shaft 20 and/or one or more discrete wall regions of the shaft 20.

[0059] Hence it is contemplated that the middle elastomer layer **410** may form any portion of a wall of the shaft **20** without necessary forming any other portion or wall of the shaft. Thus, for example, it is contemplated that middle elastomer layer **410** may, at any given cross-section of the shaft **20**, form: (a) wide wall **150** and not wide wall **160** and/or narrow walls **170** and **180**, (b) 5 narrow wall **170** and not narrow wall **180** and/or wide walls **150** and **160**, (c) narrow wall **170** and wide wall **150** but not narrow wall **180** nor wide wall **160**, (d) narrow wall **170** and **180** but not wide walls **150** and **160**, (e) wide walls **150** and **160** but not narrow walls **170** and **180**, and (f) narrow wall **180** and wide wall **150** but not narrow wall **170** nor wide wall **160**.

[0060] With respect to the longitudinal positioning of the middle elastomer layer reference is made to FIG. 21. Illustrated in FIG. 21 is a hockey stick **10** having a longitudinal length (L-HS), a shaft **20** having a longitudinal length (L-S), a first longitudinal length (L1) extending from the lower end of the shaft **20** or hockey stick **10** (i.e., including the blade **30**), and a second longitudinal length (L2) extending upward from the termination of the first longitudinal length (L1) to the upper terminal end of the shaft **20**. It is preferable that at least a portion of the middle 15 elastomer layer **420** reside within longitudinal length L1; where L1 = L-HS, even more preferably where L1 = $0.75 \times L-HS$, even more preferably where L1 = $0.5 \times L-HS$, even more preferably where L1 = $0.25 \times L-HS$, yet even more preferably where L1 is $0.20 \times L-HS$, yet even more preferably where L1 is $0.15 \times L-HS$, yet even more preferably where L1 is $0.1 \times L-HS$. Alternatively, it is preferable that at least a portion of the middle elastomer layer **420** reside within 20 longitudinal length L1; where L1 = L-S, even more preferably where L1 = $0.75 \times L-S$, even more preferably where L1 = $0.5 \times L-S$, even more preferably where L1 = $0.25 \times L-S$, yet even more preferably where L1 is $0.20 \times L-S$, yet even more preferably where L1 is $0.15 \times L-S$, yet even

more preferably where L_1 is $0.1 \times L-S$. Thus, for example if the longitudinal length of the hockey stick ($L-HS$) is 63 inches and the longitudinal length of the hockey stick shaft ($L-S$) is 60 inches long, then where $L_1 = 0.15 \times L-HS = 9.45$ inches or in other words it would be preferable that the elastomer layer, or at least a portion thereof, reside along the shaft within 9.45 inches of the tip of the blade **30**. Where $L_1 = 0.15 \times L-S = 9$ inches or in other words it would be preferable that the elastomer layer, or at least a portion thereof, reside along the shaft within 9.0 inches of the terminal lower end **335** of the shaft **20**. In the exemplary construction lay-up described , it has been found that the employment of an 8 inch elastomer sheet, formed of the above-identified exemplary elastomer, extending from the terminal lower end **335** of the shaft upwards and around each of the four sides or walls of the shaft **20** is capable of providing suitable results.

[0061] FIGs. 14 and 15 are cross-sectional views taken along line 14---14 and line 15--15 of FIG. 3 and illustrate in more detail the construction configurations of the hockey stick blade **30**. It is to be understood that the configurations illustrated therein are exemplary and various aspects, such as core element **400** configurations or other internal structural configurations, illustrated or described in relation to the various constructions, may be combined or otherwise modified to facilitate particular design purposes or performance criteria. The construction of the blade **30** will now be described with reference to FIG. 16C, which is a flow chart detailing preferred steps for manufacturing the hockey stick blade **30**. Generally, one or more plies of fibers **450**, preferably uni-directional substantially parallel fibers pre-impregnated with a resin matrix as previously described, are wrapped over one or more core elements **400** having the general shape of the hockey stick blade **30** (step 630) to form an initial blade pre-form. The core elements **400** may be comprised or wholly formed of: (1) formulations of expanding syntactic or non-syntactic foam

such as polyurethane, PVC, or epoxy, (2) wood, (3) elastomer or rubber, and/or (4) bulk molding compound (i.e. non-continuous fibers disposed in a matrix or resin base material, which when cured become rigid solids). Thus, it is contemplated there be multiple core elements **400** of which some may be made of a first material, for example foam, while others may be made of second

5 material, for example an elastomer or rubber.

[0062] After the initial blade pre-form is formed a spacer element **470** is butted up against the rear of the initial blade pre-form such that the spacer element is positioned to occupy the heel region of the blade and additional plies of fibers overlain to form a secondary blade pre-form (Step 635). The spacer element **470** is dimensioned to generally correspond to the outer dimensions of

10 the lower regions of the shaft **20** configured to mate with the blade. The spacer element **470** is then removed from the secondary blade pre-form (step 640). FIG. 17 is a diagram that illustrates the spacer element **470** being removed from the pre-cured hockey stick blade pre-form.

[0063] FIG. 16A is a flow chart detailing preferred steps for constructing a unitary hockey stick by joining the cured hockey stick shaft (step 645) described above with the un-cured

15 secondary hockey stick blade pre-form (step 650). Generally once the spacer element **470** is removed the cured hockey stick shaft **20** is inserted into the space at the heel section **140** previously occupied by the spacer element **470** between the front and back walls **90** and **100** of the pre-cured hockey stick blade pre-form as illustrated in FIG. 18 (step 655). Additional plies of fibers may be overlain about the blade and around the heel and lower end region of the shaft to

20 cover any gaps around the edges or to reinforce any weak regions around for example the heel region. The cured shaft and the un-cured blade pre-form are inserted into the a female mold configured to (a) received the uncured blade pre-form and at least a portion of the lower region of

the cured shaft and (b) having the desired exterior shape of the hockey stick blade (step 660). FIG. 19 is diagrams illustrating the un-cured hockey stick blade and the cure hockey stick shaft assembled in the open mold prior to molding and FIG. 20 is an illustration of the hockey stick blade and cured hockey stick shaft assembled in the closed mold prior to curing. Once the mold 5 is closed heat is applied and the blade is cured around the interposed lower region of the shaft (step 670) to form a unitary one-piece composite hockey stick having a hollow tubular shaft that extends internally within the front and back walls of the blade. The hockey stick is then removed from the mold and finished for example via painting or decaling or perhaps sanding or grinding any imperfections out from the molded finish.

10 [0064] While there has been illustrated and described what are presently considered to be preferred embodiments and features of the present invention, it will be understood by those skilled in the art that various changes and modifications may be made, and equivalents may be substituted for elements thereof, without departing from the scope of the invention. For example, it is contemplated that the composite hockey stick shaft having a middle elastomer layer **420** disclosed 15 and taught herein be employed in hockey stick shaft configurations disclosed and taught in co-pending and owned U.S. Patent Serial Number 10/439,652 filed on May 15, 2003. In addition, it is contemplated, for example, that the composite hockey stick shaft having a middle elastomer layer **420** disclosed and taught herein be employed in hockey sticks having the composite blade structures disclosed and taught in co-pending and owned U.S. Patent Serial Number 10/439,652 20 filed on May 15, 2003.

[0065] In addition, many modifications may be made to adapt a particular element, feature or implementation to the teachings of the present invention without departing from the central

scope of the invention. Therefore, it is intended that this invention not be limited to the particular embodiments disclosed herein, but that the invention include all embodiments falling within the scope of the appended claims. In addition, it is to be understood that various aspects of the teachings and principles disclosed herein relate configuration of the blades and hockey sticks and 5 component elements thereof. Other aspects of the teachings and principles disclosed herein relate to internal constructions of the component elements and the materials employed in their construction. Yet other aspects of the teachings and principles disclosed herein relate to the combination of configuration, internal construction and materials employed therefor. The combination of one, more than one, or the totality of these aspects defines the scope of the 10 invention disclosed herein. No other limitations are placed on the scope of the invention set forth in this disclosure. Accordingly, the invention or inventions disclosed herein are only limited by the scope of this disclosure that supports or otherwise provides a basis, either inherently or expressly, for patentability over the prior art. Thus, it is contemplated that various component elements, teachings and principles disclosed herein provide multiple independent basis for 15 patentability. Hence no restriction should be placed on any patentable elements, teachings, or principles disclosed herein or combinations thereof, other than those that exist in the prior art or can under applicable law be combined from the teachings in the prior art to defeat patentability.
